Overview

Typical batteries have a solid membrane between the anode and the cathode, compared with liquid-metal batteries where the anode, the cathode and the membrane are liquids. The sodium at the core serves as the anode, meaning that it donates electrons to the external circuit. The sodium is separated by a separator (BASE). Pure sodium presents a hazard, because it spontaneously burns in contact with air and moisture, thus safety features are required to avoid direct contact with water and oxidizing atmospheres. Early on the
